

## Notes on Biofuel Trade Module

Chad Hellwinckel and Daniel De La Torre Ugarte

June 20 2017

### Ethanol Trade Module

US ethanol trade is modeled as a system of three estimated equations (imports, exports and domestic ethanol demand). Exogenous variables include world sugar price and world oil price and US ethanol price. Endogenous variable is corn price.

Shocks enter the module through a change in the baseline situation that would impact corn prices. Corn prices impact imports, exports, and domestic demand, and therefore total demand for corn. Total demand for corn then impacts corn price. The model simultaneously solves until an equilibrium is achieved (figure 1).

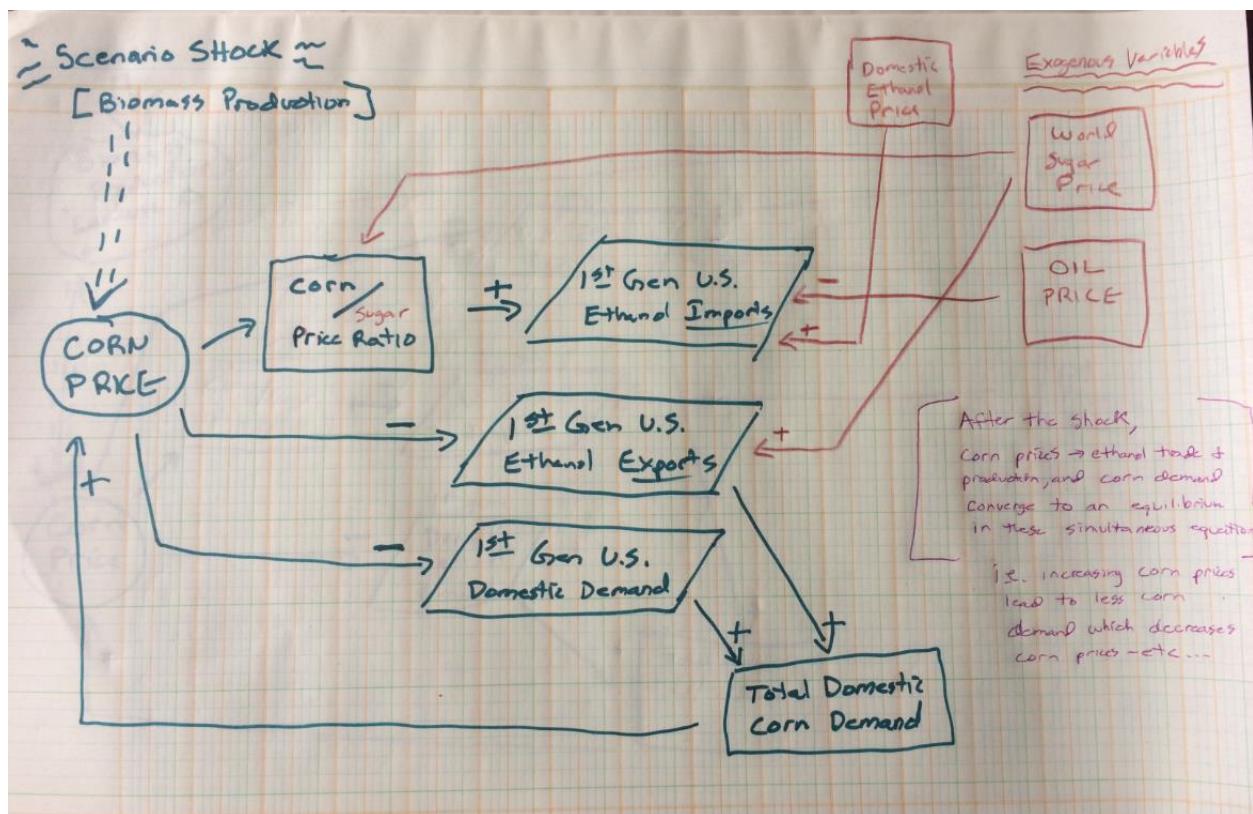

Figure 1: Ethanol Trade Module

$$\begin{aligned} \text{US Ethanol Exports} = & -21825 + (1180) * \text{Sugar Price} + (671.67) * \text{export structural change} \\ & + (10.88) * \text{year} + (-72.92) * \text{corn price lag} \end{aligned}$$

Where,

export structural change is a dummy variable changed to one in 2009 when ethanol exports went up dramatically. We keep this at 1 for all simulations.

And 'year' is a time trend equal to the 4 digit year.

The AUTOREG Procedure

$$\begin{aligned} \text{US Ethanol Imports} = & -789.38 + (17.88) * \text{corn to sugar price ratio} + (-5.05) * \text{oil price} \\ & + (580.14) * \text{domestic ethanol price} \end{aligned}$$

We also wanted to make domestic ethanol demand change as corn prices changed. To figure the baseline, domestic ethanol demand is simply total ethanol demand minus export ethanol demand, but in simulations;

$$\text{Corn grain demand of US Domestic Ethanol Demand} = \text{Baseline corn grain demand of Domestic ethanol demand} * (1.0 + \text{elasticity of corn grain demand} * \% \text{ change in corn price})$$

Where,

Elasticity of corn grain demand = -0.35

## Biodiesel Trade Module

US biodiesel trade is modeled as a system of two equations (US exports, US imports), with 3 exogenous variables (palm oil price, Argentine Biodiesel production, RFS level of biodiesel), and one endogenous variable (soybean price).

Shocks enter the module through a change in the baseline situation that would impact soybean prices. Soybean prices impact imports, exports, and therefore total demand for soybeans. Total demand for soybeans then impacts soybean price. The model simultaneously solves until an equilibrium is achieved (figure 1).

$$\begin{aligned} \text{US Biodiesel Exports} = & 1100 + (-0.00023) * \text{argentine biodiesel production} \\ & + (-29316) * \text{soybean to palm oil price ratio} \end{aligned}$$

## Programming

There are three new subscripts added to POLYSYS for the Biofuel trade module;

**Setethtrade.for**, which is ‘called’ from **setusda.for**. This reads in the exogenous variables from the **ethtrade.txt** file. To change exogenous variables read in the baseline, change here.

Baseline given exogenous variables entered in the input file : /input/bio/ethtrade.txt

**Ethtrade.for**, which is called from **grains.for**. This has the equations for both the baseline and simulation runs for ethanol trade.

**Biodiestrad.for**, which is called from **grains.for**. This has the equations for both the baseline and simulation for biodiesel trade.

Baseline calculations given exogenous variable values currently in ethtrade.txt. These can be changed, and actually should be changed to projected estimates found in FAO, EIA, IEA, etc.

**There are 2 new index switches in SIM.INS for the biotrade module, indices [101] and [102]:**

```
2<- 0 IF NO CHANGE FROM BASELINE; 1 IF ALLOW DOMESTIC CORN DEMAND FOR ETHANOL TO FALL UNDER HIGH PRICES,2 IF USE NEW BIOENERGY TRADE MODULE[101]
0<- 0 IF READ IN BASELINE EXPORTS/IMPORTS IN BIOTRADE MODULE; 1 IF ALLOW BIOTRADE MODULE TO COMPUTE[102]
```
